October 1, 2019

This project

 Combines a formal definition of an anchoring mechanism (AM) from econometric learning

with a standard macro model of monetary policy

- ⇒ Explains current monetary policy as a concern to keep expectations anchored
 - Reinterprets Great Inflation as a period of unanchored expectations
 - Reevaluates optimal monetary policy

- 1 Related literature
- 2 Intuition: What is anchoring and why should it matter?
- 3 A FORMAL NOTION OF ANCHORING
- 4 Model with anchoring mechanism
- 5 SIMULATIONS

PHILLIPS CURVE

$$\pi_t = \beta \hat{\mathbb{E}}_t \pi_{t+1} + \kappa \mathbf{x}_t$$

- $\pi_t = \text{inflation}$
- $x_t = \text{output gap}$
- $\hat{\mathbb{E}}_t$ = expectation-operator (not necessarily rational)

Suppose a negative demand shock:

$$\pi_{t} = \beta \hat{\mathbb{E}}_{t} \pi_{t+1} + \kappa \mathbf{x}_{t} \downarrow$$

If expectations do not move:

$$\pi_{t} = \beta \hat{\mathbb{E}}_{t} \pi_{t+1} + \kappa \mathbf{x}_{t} \downarrow$$

If seeing π_t , expectations adjust:

$$\pi_{t} = \beta \hat{\mathbb{E}}_{t} \pi_{t+1} + \kappa \mathbf{x}_{t}$$

$$\downarrow \downarrow \qquad \downarrow$$

Keeping expectations stable may be desirable

 \rightarrow "Anchored": notion of stable expectations

(Flattening PC due to anchored expectations, Hooper et al (2019))

A LEARNING MODEL OF EXPECTATION FORMATION

Suppose firms and households

• observe everything up to time t

do not observe future variables

 $\bullet~$ KEY: are unsure about the long-run mean of inflation, $\bar{\pi}$

Agents construct one-period-ahead inflation forecasts as

$$\hat{\mathbb{E}}_t \pi_{t+1} = \bar{\pi}_{t-1} + bs_t \tag{1}$$

 $\bar{\pi} = \text{estimate of inflation drift (= long-run mean, "target")}$

 $\hat{\mathbb{E}} = \text{subjective}$ expectation operator (not rational expectations, $\mathbb{E})$

b = matrix of constants

s = shocks

DEFINITION: ANCHORING MECHANISM

$$\bar{\pi}_t = \bar{\pi}_{t-1} + k_t \underbrace{\left(\pi_t - (\bar{\pi}_{t-1} + bs_{t-1})\right)}^{\text{short-run forecast error}}$$
 (2)

$$k_{t} = \begin{cases} \frac{1}{k_{t-1}+1} & \text{if} \quad \widehat{|\hat{\mathbb{E}}_{t-1}\pi_{t} - \mathbb{E}_{t-1}\pi_{t}|/\sigma_{s}} \leq \bar{\theta} \\ \bar{g} & \text{otherwise} \end{cases}$$
 (3)

Equation (3): endogenous gain

- Carvalho et al (2019)
- Difference to standard econometric learning

	 _	_	_	
Expectations				

• Expectations unanchored = when agents choose **constant** gains

- 1 Related literature

- 4 Model with anchoring mechanism
- 5 SIMULATIONS

THE MODEL

Households maximize

$$\hat{\mathbb{E}}_t^i \sum_{s=0}^{\infty} \beta^s \bigg(\mathsf{U}(\mathsf{C}_s^i) - \mathsf{v}(\mathsf{H}_s^i) \bigg)$$

Household budget constraint:

 $B_t^i < (1+i_{t-1})B_{t-1}^i + W_tH_t^i + \Pi_t^i - T_t - P_tC_t^i$

Firms: monopolistic competition in varieties C^{i} , Calvo price setting

Expectations: $\hat{\mathbb{E}}$ as in (1)

(4)

(5)

3-Equation New Keynesian Model

$$\mathbf{x}_{t} = -\sigma \mathbf{i}_{t} + \hat{\mathbb{E}}_{t} \sum_{T=t}^{\infty} \beta^{T-t} ((\mathbf{1} - \beta) \mathbf{x}_{T+1} - \sigma(\beta \mathbf{i}_{T+1} - \pi_{T+1}) + \sigma r_{T}^{n})$$

$$oldsymbol{i}_t = \psi_\pi \pi_t + \psi_{\mathsf{X}} \mathbf{x}_t + oldsymbol{ar{i}}_t$$

"Long-horizon forecasts" \rightarrow agents do not know the model

 $\pi_{t} = \kappa \mathbf{x}_{t} + \hat{\mathbb{E}}_{t} \sum_{T=1}^{\infty} (\alpha \beta)^{T-t} (\kappa \alpha \beta \mathbf{x}_{T+1} + (\mathbf{1} - \alpha) \beta \pi_{T+1} + \mathbf{u}_{T})$

^{*} Carvalho et al (2019)'s estimates. Exception: $\bar{\theta}=$ 0.029.

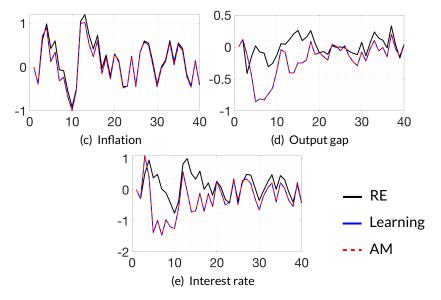

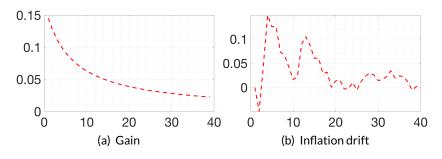

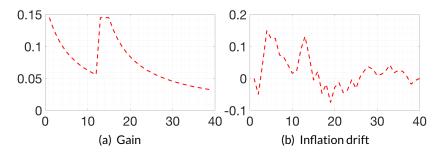

FIGURE: Rational expectations (RE), learning and anchoring mechanism (AM)

 $\operatorname{Figure}\colon$ Well anchored expectations: decreasing gain

Decreasing $\bar{\theta}$: an unanchored case

 ${\tt Figure:}\ \bar{\theta}={\tt 1.}\ {\tt Unanchored}\ {\tt expectations:}\ {\tt constant}\ {\tt gain}$

 $\mathrm{Figure:}\ \bar{\theta} = 0.029.$ Carvalho et al's estimate extremely unanchored!

GAIN WHEN VARYING TAYLOR-RULE COEFFICIENTS

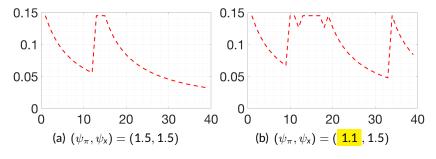

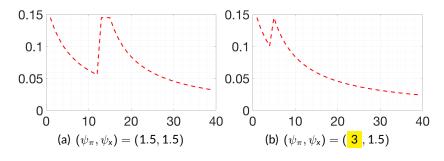

FIGURE: Less aggressive on inflation

 $\operatorname{Figure} :$ More aggressive on inflation

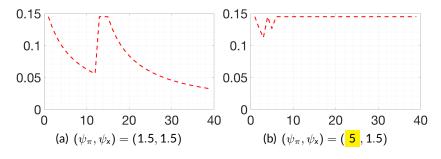

FIGURE: Too aggressive on inflation?

Today's conclusion and work ahead

- \bullet Formal definition of anchoring + macro model with monetary policy
 - → investigation of new constraint on monetary policy
- Next steps
 - Write and solve monetary policy problem
 - Estimate model

Thank you!

DERIVATIONS

Household FOCs

$$\hat{C}_t^i = \hat{\mathbb{E}}_t^i \hat{C}_{t+1}^i - \sigma(\hat{l}_t - \hat{\mathbb{E}}_t^i \hat{\pi}_{t+1})$$
(9)

$$\hat{\mathbb{E}}_t^i \sum_{s=0}^{\infty} \beta^s \hat{C}_t^i = \omega_t^i + \hat{\mathbb{E}}_t^i \sum_{s=0}^{\infty} \beta^s \hat{Y}_t^i$$
(10)

where a hat denotes log-linear approximation and $\omega_t^i \equiv \frac{(1+i_{t-1})B_{t-1}^i}{P_tY^*}$.

- Solve (9) backward to some date t, take expectations at t
- Sub in (10)
- Aggregate over households i
- \rightarrow Obtain (6)

Compact notation

$$z_t = A_1 f_{a,t} + A_2 f_{b,t} + A_3 s_t$$
$$s_t = P s_{t-1} + \epsilon_t$$

$$z_t \equiv$$

$$z_t \equiv \begin{pmatrix} \pi_t \\ x_t \\ i_t \end{pmatrix} \qquad s_t \equiv \begin{pmatrix} r_t^n \\ \overline{i}_t \\ u_t \end{pmatrix}$$
